## LIMESTONE AND DOLOMITE DISTRIBUTION IN PENNSYLVANIA

COMMONWEALTH OF PENNSYLVANIA  
DEPARTMENT OF  
CONSERVATION AND NATURAL RESOURCES  
BUREAU OF TOPOGRAPHIC AND GEOLOGIC SURVEY  
[www.dcnr.state.pa.us/topogeo](http://www.dcnr.state.pa.us/topogeo)

- Limerock Quarry
- Eastern Pennsylvania
- Extensive Karst
- Impacts to residential and State properties due to sinkholes
- Determine zone of influence in aquifer due to dewatering
- Predict effect of mitigation strategies on quarry infiltration

# Key Features

# Quarry Infiltration: 5-7 MGD

# Sinkhole Damage to Property & Infrastructure

## Cause:

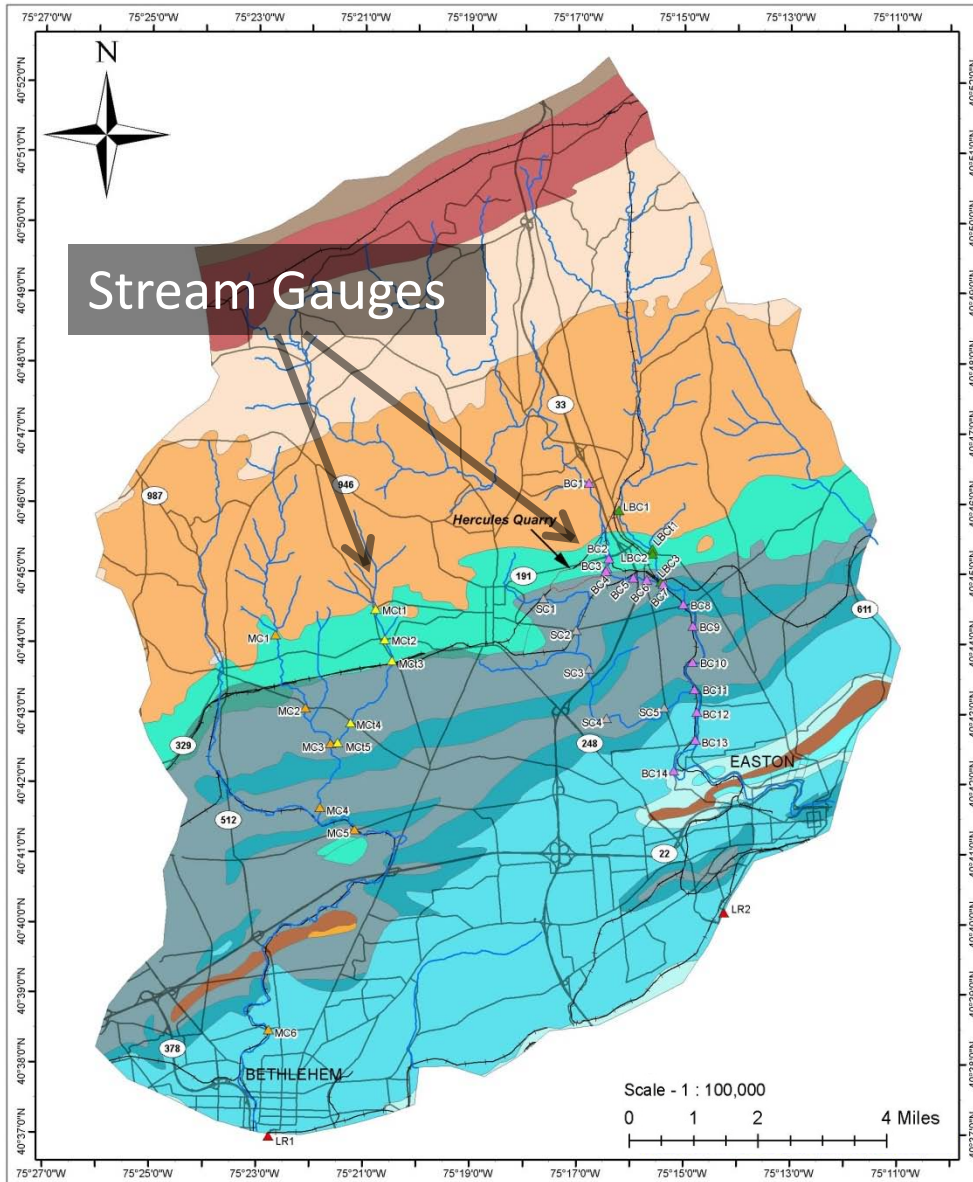

Presumed to be due to drawdown caused by quarry dewatering.

## Primary modeling objective:

Delineate dewatering zone of influence.

# Geology & Hydrology

- Quarry situated at contact between carbonate and non-carbonate (shale) units.
- Numerous streams loose water to aquifer once they cross into carbonates.
- Extensive and widespread sinkhole development in carbonate region.

## Geology

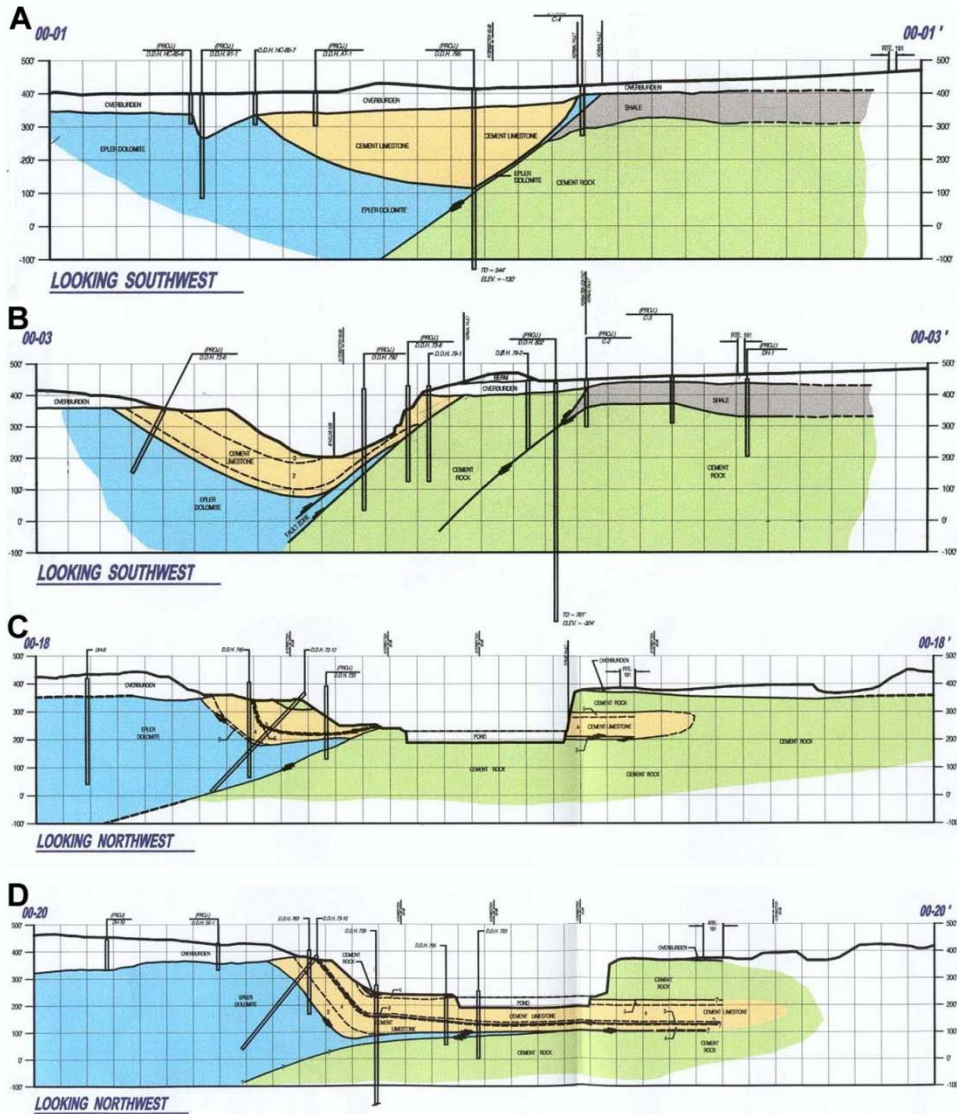

### Carbonate Units

- Allentown Formation
- Epler Formation
- Franklin Marble
- Jacksonburg Formation
- Leithsville Formation
- Ontelaunee Formation
- Rickenbach Formation

### Noncarbonate Units

- Gneiss
- Hardyston Formation
- Shawangunk Formation
- Martinsburg Formation
- Bushkill Member
- Pen Argyl Member
- Ramseyburg Member

# 3D Geologic Complexities

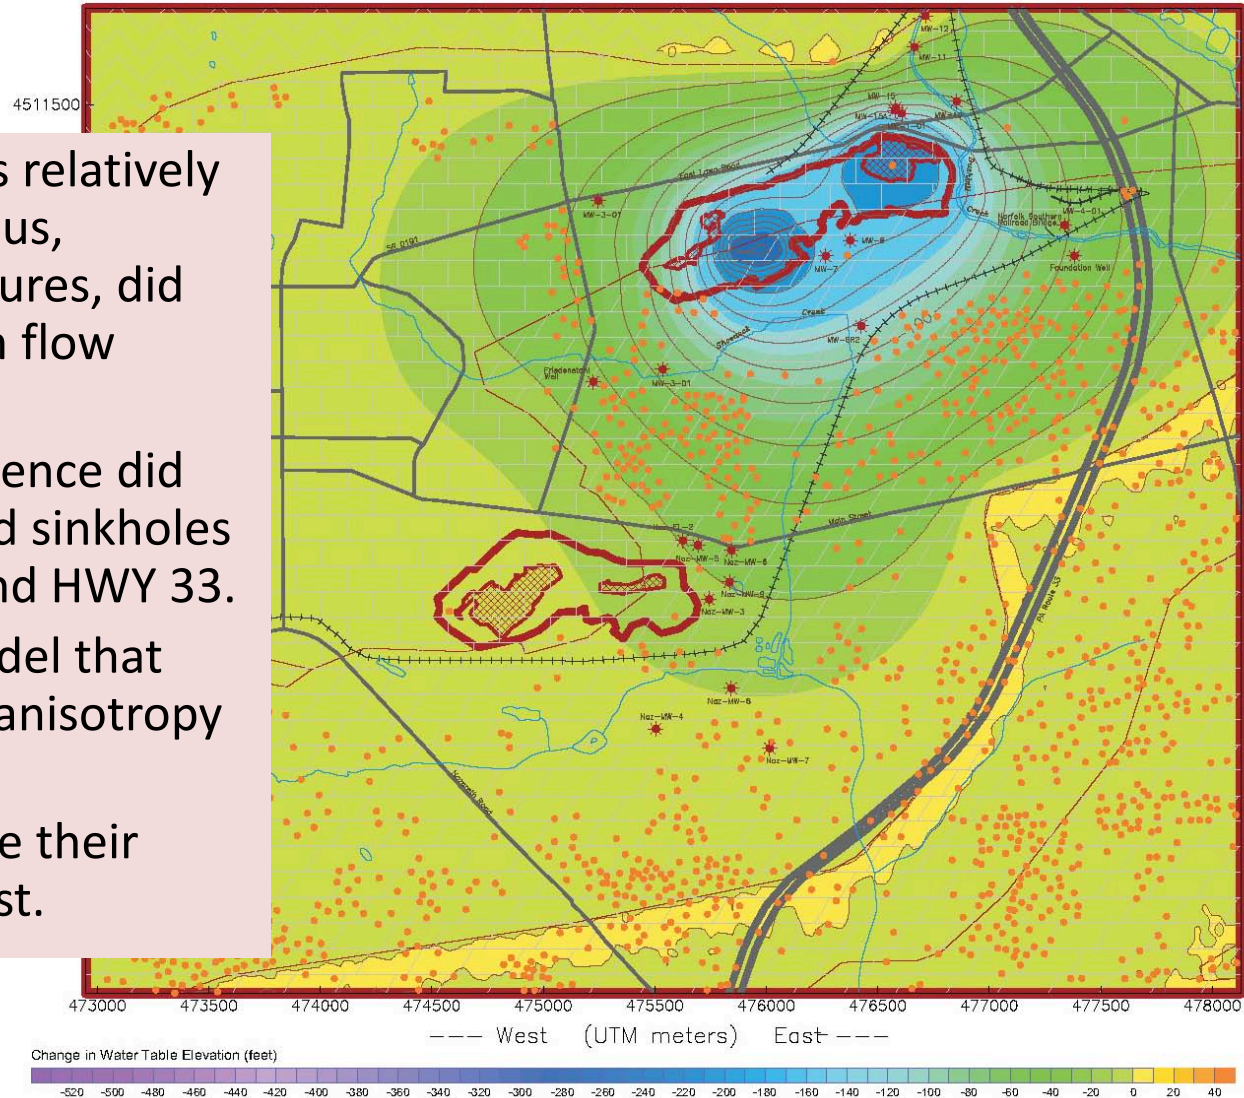

- Model was 3D, containing 2 layers representing the ????
- Continue with description here.

# Previous Modeling Limitations

Predicted Zone of Influence: Hercules Only

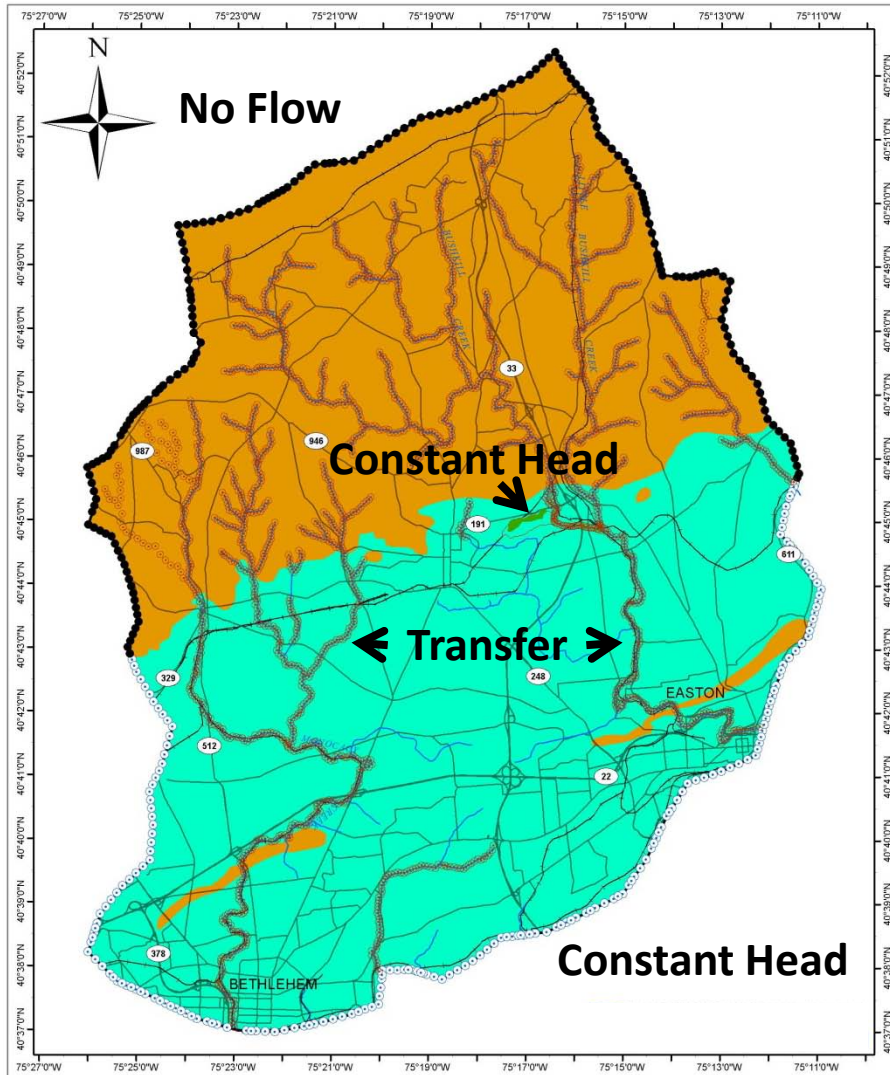

- Previous modeling was relatively simplistic, homogeneous, isotropic, no karst features, did not account for stream flow losses.
- Predicted zone of influence did not extend to observed sinkholes between the quarry and HWY 33.
- USGS completed a model that attempted to address anisotropy due to karst.
- Quarry asked to update their model and include karst.

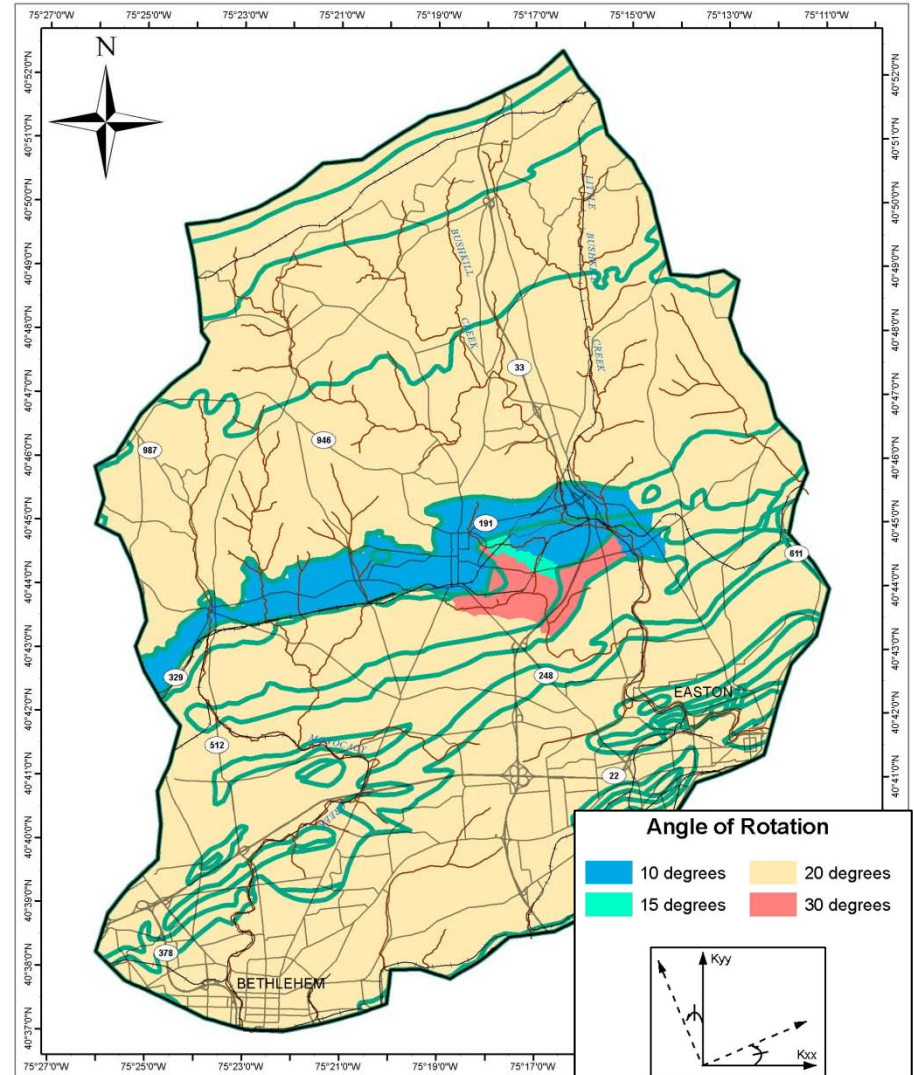

# Model Design: Streams & Anisotropy

## Boundary Conditions

## Anisotropy Assignment

# Model Design: Karst Conduits

- Model was designed using the software FEFLOW™
- Conduits were assigned as 1D linear features
- Connected seeps in quarry floor to sinkholes in creek where connection and velocity was established by tracing.
- Conduit flow simulated using the Manning-Strickler eq.
- Matrix flow simulated using the Darcy eq.

## Conduit Parameters GWM - Layer Two

MAP SHOWS HOW THE AREA CHANGES OVER THE LENGTH OF THE CONDUITS. THE CONDUITS HAVE A CONSTANT ROUGHNESS COEFFICIENT ASSIGNED AT A VALUE OF 0.1776 (M0.33/S).

### Cross-Sectional Area

3 m <sup>2</sup>	25 m <sup>2</sup>
6 m <sup>2</sup>	28 m <sup>2</sup>
7 m <sup>2</sup>	35 m <sup>2</sup>
9 m <sup>2</sup>	41 m <sup>2</sup>
14 m <sup>2</sup>	42 m <sup>2</sup>
16 m <sup>2</sup>	57 m <sup>2</sup>
21 m <sup>2</sup>	

### Conduit Travel-Time

47.7 hours
18.9 hours

### Map Features

State Road
Railroad
Creeks
Hercules Quarry Rim (2006)

Scale - 1:10,000

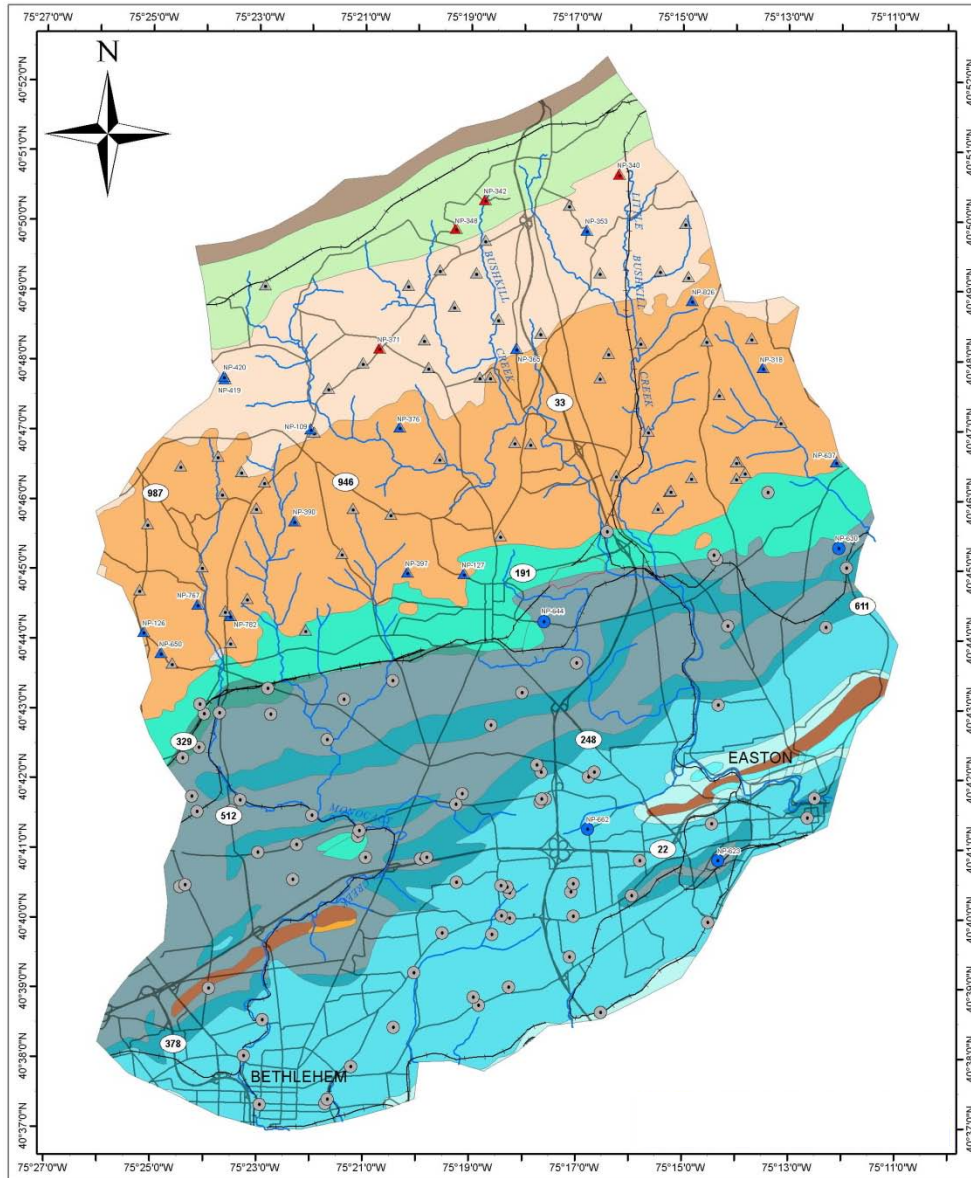

Projection - UTM NAD 1983 Zone 18N

# Model Results: Lined vs. Unlined Stream

## Model-Simulated Zone of Influence

# Scenario Analyses

Table 7. Magnitude and source of Quarry discharge simulated for the current conditions, stream lining, and two versions of the build down model scenarios.

Scenario	Components of Simulated Quarry Discharge $m^3/s$ (cfs)						
	Total	Jacksonburg	Epler	Aquifer	River	Streambed	Sinkholes
Current Conditions	2.47 (87.4)	0.14 (4.8)	2.34 (82.5)	0.54 (19.1)	1.93 (68.3)	0.41 (14.5)	1.52 (53.8)
1 – Lined Stream	1.18 (41.6)	0.11 (4.0)	1.06 (37.6)	1.18 (41.6)	0.00	0.00	0.00
2a – Build Down	3.26 (115.2)	0.19 (6.8)	3.07 (108.4)	1.00 (35.5)	2.26 (79.7)	0.74 (26.0)	1.52 (53.8)
2b – Build Down	3.81 (134.7)	0.20 (7.0)	3.62 (127.7)	0.72 (25.4)	3.09 (109.2)	0.57 (20.1)	2.52 (89.1)
3 – Plugged Epler	0.59 (21.0)	0.18 (6.4)	0.41 (14.63)	NC	NC	NC	NC

- Used model to simulate how mitigation strategies and potential quarry build-down scenarios would likely change the magnitude and source of discharge into the quarry.
- Ultimately recommended that sealing the quarry floor would have a significantly greater effect on reducing both quarry discharge and the zone-of-influence in the aquifer than other mitigation strategies.

# Comparing Predictions: Zone of Influence

Model with karst, anisotropy, and stream flows

Simplistic Model homogeneous, isotropic

# Summary

---

- Model successfully incorporated observed karst conduit features and inferred anisotropies as well as observed stream flow gains and losses.
- Incorporating the hydrogeologic complexities fostered a strong calibration to observed heads and stream flows.
- Strong calibration and incorporation of observed complexities increased confidence in the predictions with the State.
- Simulated zone of influence was accepted by State and used as a basis for negotiating terms for consent order-driven mitigation of impacts from sinkhole development associated with dewatering.
- Model also proved to be a useful tool for evaluating future design and build-down scenarios.
